ABSTRACT

Conflict-free Replicated Data Types (CRDTs) can simplify the design of deterministic eventual consistency. Considering the several CRDTs that have been deployed in production systems, counters are among the first. Counters are apparently simple, with a straightforward *inc/dec/read* API, but can require complex implementations and several variants have been specified and coded. Unlike sets and registers, that can be adapted to operate inside maps, current counter approaches exhibit anomalies when embedded in maps. Here, we illustrate the anomaly and propose a solution, based on a new counter model and implementation.

Keywords

Distributed Counting, Eventual Consistency, CRDTs.

1. INTRODUCTION

In order to support high-availability and low response latency in geo-replicated data storage systems, developers have successfully explored relaxed consistency models, such as eventual consistency [8, 1], and supporting frameworks, such as conflict-free replicated data types (CRDTs) [6, 7]. This trend towards fast querying and data manipulation at the edge, possibly under partitions, will likely become more prevalent with the growth of IoT deployments.

Complex CRDT deployments require mechanisms for composing together several base data types. A common strategy [5] is to define a replicated map data structure that maps keys to CRDT instances. In the Riak data store, maps can store sets, registers, flags, counters and even, recursively, other maps [3] (as they are CRDTs themselves). Maps need to support the addition and removal of entries (key bindings), and allow data type dependent updates over the stored CRDT instances.

2. EMBEDDED COUNTERS ANOMALY

In order to provide a sound semantics for key removal, CRDT maps behave in a way such that a non-present key (e.g., after removal), when fetched returns the default initial state, i.e., bottom, of the embedded CRDT. Efficient implementations require the storable CRDT data types to provide a special *reset* operation that brings the instance back to bottom, which need not be stored in the map, while allowing the map meta-data to remember the reset state in an efficient way, without requiring any per-key metadata; i.e., no per-key tombstone. Technically this is done by keeping a global causal context for the whole map, that is common to all the recursively embedded CRDTs. This can be thought of as a *observed-reset*, in the sense that all operations that have been observed to be applied to the map when the reset is issued, should be equivalently reset on another instance which observes the reset upon a join. Below is an example of a correct reset over an *add-wins set*.

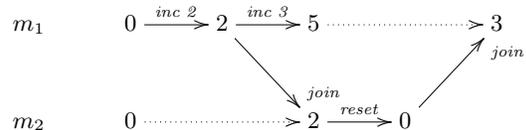

```
m1["friend"].add("alice");
m2.join(m1);
m2.remove("friend"); // m2: {}
m1["friend"].add("bob");
m1.join(m2); // m1: {"friend" -> {"bob"}}
```

After `m2.join(m1)` both replicas hold a mapping to a `AWSet` with a single “alice” element. Once replica `m2` removes the “friend” entry from the map, the set becomes implicitly empty. Concurrently, replica `m1` adds a new element “bob” to the set. Later, after joining the two replicas, we see that the *reset*, implicitly called on the set when removing the entry, only undoes the `add("alice")` and not the `add("bob")`.

We now change the example to illustrate the ideal (sound) semantics when counters are embedded. Initially we increment by 2 the “friend” entry and then we concurrently remove it and increment by 3. Ideally, removing the entry should undo the “increment by 2”, which when merged to `m1`, would leave the “increment by 3” as the only remaining operation, and counter value of 3.

```
m1["friend"].inc(2);
m2.join(m1); m2.remove("friend");
m1["friend"].inc(3);
m1.join(m2); // m1: {"friend" -> 3}
```

The desired counter evolution would be:

$$\begin{aligned}
\text{Counter} &= (\mathbb{I} \times \mathbb{N} \leftrightarrow \mathbb{N} \times \mathbb{N}) \times (\mathbb{I} \leftrightarrow \mathbb{N}) \\
\perp &= (\{\}, \{\}) \\
\text{inc}_i(s) &= \text{upd}_i(s, (1, 0)) \\
\text{dec}_i(s) &= \text{upd}_i(s, (0, 1)) \\
\text{upd}_i((m, c), u) &= (m' \{d \mapsto m'(d) + u\}, c') \text{ where } d = (i, c'(i)), \\
&\quad (m', c') = \begin{cases} \text{fresh}_i((m, c)) & \text{if } (i, c(i)) \notin \text{dom } m \\ (m, c) & \text{otherwise} \end{cases} \\
\text{fresh}_i((m, c)) &= (m \{(i, c(i) + 1) \mapsto (0, 0)\}, c \{i \mapsto c(i) + 1\}) \\
\text{reset}_i((m, c)) &= (\{\}, c) \\
\text{value}_i((m, c)) &= \sum_{d \in \text{dom } m} \text{fst } m(d) - \text{snd } m(d) \\
(m, c) \sqcup (m', c') &= (\{d \mapsto m(d) \sqcup m'(d) \mid d \in \text{dom } m' \cap \text{dom } m\} \cup \\
&\quad \{(j, n), v) \in m \mid n > c'(j)\} \cup \{(j, n), v) \in m' \mid n > c(j)\}, \\
&\quad c \sqcup c')
\end{aligned}$$

Figure 1: Resettable Counter, replica i .

counter instance when the corresponding key is removed. Since CRDTs embedded in maps all share a common causal context, removing a map entry effectively removes all the state associated to the counter instance.

Finally, the join function will: look for entries in common among the two maps m, m' and join the corresponding values by taking the pairwise maximum of the two *positive-negative* values; and for entries that are present only in one map, only those whose dot was never seen in the other causal context are preserved. This is done by checking if the number n in the dot (j, n) is strictly higher than the highest entry known for j in the other causal context. The joined causal context is simply obtained, as usual for version vectors, by coordinate-wise maximum between maps c and c' .

6. FINAL REMARKS

The new counter design we propose in this paper addresses the problem that prevented counters to be embedded in a map and still provide a *reset* that would correctly remove all past operations, to be used when removing an entry from the map. Even when not embedded, current counters still have that problem if applications require a reset operation.

The solution we propose is efficient, in terms of meta-data cost, under a *remove-wins* semantics. The alternative, *add-wins*, that protects operations from being cancelled by concurrent resets, has considerable meta-data cost. This cost can be reduced by a system design that only creates *fresh* entries after the counter state is sent to other replicas, possibly accepting the trade-off of a low rate of dissemination and less overall recency. Further research is needed, to evaluate this cost and to attempt garbage collection of entries possibly through *reset* together with some coordination.

Reference implementations for the various counters, including the Riak DT counter (CCounter) and the proposed counter (RWCounter), are publicly available in GitHub [2] for C++. *Rust* implementations are under development.
